Homework 2: Linear Regression

INSTRUCTOR: DANIEL L. PIMENTEL-ALARCÓN   DUE 10/15/2020

GO GREEN. AVOID PRINTING, OR PRINT 2-SIDED MULTIPAGE.

In class we studied the linear regression model $\mathbf{y} = \mathbf{X}\boldsymbol{\theta}^\star + \boldsymbol{\epsilon}$, under the *homoskedastic* assumption $\boldsymbol{\epsilon} \sim \mathcal{N}(\mathbf{0}, \sigma^2\mathbf{I})$. In this homework you will derive the same results for the slightly more general *heteroskedastic* model where $\boldsymbol{\epsilon} \sim \mathcal{N}(\mathbf{0}, \boldsymbol{\Sigma}^\star)$. Each subproblem is worth 10 points.

Problem 2.1. Derive an expression for the coefficient vector $\boldsymbol{\theta}$ that minimizes the mean squared error, i.e.,

$$\arg\min_{\boldsymbol{\theta}} \ \|\mathbf{y} - \mathbf{X}\boldsymbol{\theta}\|_2^2.$$

Problem 2.2. Derive an expression for the maximum likelihood estimator (MLE) of $\boldsymbol{\theta}^\star$, i.e.,

$$\arg\max_{\boldsymbol{\theta}} \ \mathbb{P}(\mathbf{y}, \mathbf{X}|\boldsymbol{\theta}, \boldsymbol{\Sigma}^\star)$$

Problem 2.3. What is the distribution of the MLE of $\boldsymbol{\theta}^\star$?

Problem 2.4. Given a new sample with feature vector $\mathbf{x}$, what is the MLE of the response, $\hat{y}$?

Problem 2.5. Given a new sample with feature vector $\mathbf{x}$, what is the distribution of the MLE $\hat{y}$?

Problem 2.6. Derive an expression for the MLE of $\boldsymbol{\Sigma}^\star$, i.e.,

$$\arg\max_{\boldsymbol{\Sigma}} \ \mathbb{P}(\mathbf{y}, \mathbf{X}|\boldsymbol{\theta}^\star, \boldsymbol{\Sigma})$$

Problem 2.7. Consider the following vector $\mathbf{y}$, containing information about glucose level of four individuals, and the following data matrix $\mathbf{X}$ containing information about height and weight of the corresponding individuals:

$$\mathbf{y} = \begin{bmatrix} 110 \\ 140 \\ 180 \\ 190 \end{bmatrix}, \qquad \mathbf{X} = \begin{bmatrix} 180 & 150 \\ 150 & 175 \\ 170 & 165 \\ 185 & 210 \end{bmatrix}.$$

Given these data

(a) What are your maximum likelihood estimates of $\boldsymbol{\Sigma}^\star$ and $\boldsymbol{\theta}^\star$?

(b) Given a new sample with feature vector $\mathbf{x} = [175 \ \ 170]^\mathsf{T}$, what is the maximum likelihood estimate of its response $\hat{y}$?

(c) Derive a 95% confidence interval for $\hat{y}$.

(d) Would you conclude that height is a significant feature for this model? Why?

(e) Would you conclude that weight is a significant feature for this model? Why?
